

Chapter 41

Next-generation Community Hubs for Socio-economic Empowerment: A Pilot Human-centred Framework and Participatory Digital Twin Approach

Alejandro Lozano Robledo* and Domagoj Bui

Future Mobility Design Laboratory, Digital Futures, University of Cincinnati, Cincinnati, Ohio, United States of America

Abstract

The University of Cincinnati's (UC) Future Mobility Design (FMD) Lab, in collaboration with the Ohio Department of Transportation (ODOT), developed a human-centred research (HCR), data-driven methodology to help communities and decision-makers co-create future-ready hubs that integrate transportation with access to healthcare, education, employment, and other essential services. The framework includes three components: a mixed-methods approach for data collection, a hubs typology matrix based on land-use and community needs, and a translation framework that enables stakeholders to design local hubs. Outputs include nine immersive digital twins (DTs) and the Future Hub Playbook, a participatory guide for inclusive stakeholder engagement. While full co-design workshops are planned for the next research phase, this pilot highlights the potential of combining mixed-methods and simulation technologies to empower communities and facilitate inclusive planning. The framework is currently being adapted with global partners, including the MIT City Science Network, for implementation across the U.S., the Global South, and Europe.

Keywords: *Community hubs, Digital twins, Human-centred, Design, Participation*

Introduction

Rapid urbanisation and accelerating technological change are reshaping how people live, move, and access services worldwide¹. Traditional planning often overlooks local realities, perpetuating exclusion and access disparities². These complexities require a new bottom-up approach that integrates community knowledge, data, and democratized planning³. Enhancing participatory processes with digital technologies can help bridge gaps in participation and access. Future hubs, multifunctional mobility and community centres, are used in this chapter as a case study due to their systemic potential and adaptability.

¹Hannon et al., "An Integrated Perspective on the Future of Mobility," McKinsey & Company (2018) <https://www.mckinsey.com/business-functions/sustainability-and-resource-productivity/our-insights/an-integrated-perspective-on-the-future-of-mobility>.

This chapter presents a design-driven methodology developed by UC's FMD Lab, in partnership with ODOT, to co-create multifunctional, future-ready hubs that integrate transportation with essential services. Grounded in HCR and powered by DTs, the framework comprises three phases: 1. Mixed-methods methodology for participatory and context-aware data collection, 2. Translation framework to integrate data into design recommendations, and 3. Simulation tools for accessible stakeholder involvement. The research question is: How can HCR methods and emerging technologies enable participatory development of sustainable future hubs? This research contributes to participatory planning literature by embedding simulations and qualitative research into replicable, policy-aligned toolkits.

Background: Addressing Access Gaps Through Future Hubs

Global Access Inequities

Traditional car-centric planning, limited infrastructure, and exclusionary zoning have disproportionately impacted underserved communities. These environments restrict quality of life and reinforce barriers to essential services⁴. New global planning strategies emerge in response to the failures of the past and the demands of the future by addressing the diverse needs of urban, suburban, and rural populations⁵. Inclusive and participatory tools emerge as needed catalysts to bridge the access gap⁶.

Future-ready Hubs

Future hubs serve as community anchors, integrating transport with essential services like education, healthcare, recreation, and commerce. Their impacts include economic resilience, equitable access, and spatial inclusion. While established frameworks for planning exist, stakeholder engagement remains underdeveloped⁷, and few models enable communities to co-design these environments meaningfully.

Participatory and Tech-enabled Planning

Participatory co-design and stakeholder research are essential for tackling complex societal issues. These processes depend on collaborative, accessible tools that empower communities to shape planning outcomes⁸. DTs provide immersive, low-cost visualisations of spatial and social data, enabling deeper

engagement, understanding, and consensus-building. When integrated into participatory processes, they help stakeholders visualize, explore, and shape potential futures⁹.

Methods: Developing HCR and Data-driven Frameworks

Hubs Definition

To identify potential hub typologies across Ohio, an IRB-approved study was conducted using mixed methods: primary research (stakeholder interviews, surveys, site visits¹⁰) and secondary research (STEEP analysis¹¹ and trends forecasting¹²), uncovered current mobility experiences/challenges, and opportunities for future hubs (Figure 1). Data included 81 survey responses from stakeholders across Ohio¹³, 20 expert interviews from the U.S., and multiple site visits (Figure 2).

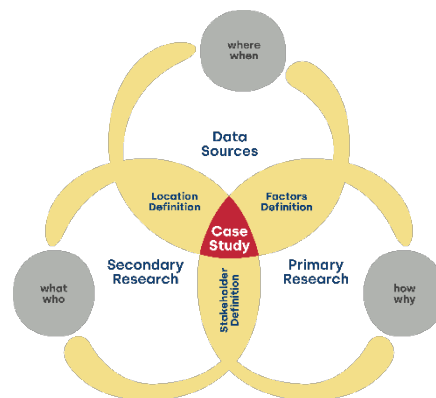

Figure 1: Case Study Definition.

Figure 2: Primary Data Collection.

These inputs revealed gaps, preferences, and infrastructure needs, leading to defining nine hub case studies and a Typology Matrix that accounted for urban, suburban, and rural land use, alongside levels of connection and size. The matrix was cross-validated with GIS data and planning tools from the UC Infrastructure Institute¹⁴ (Figure 3).

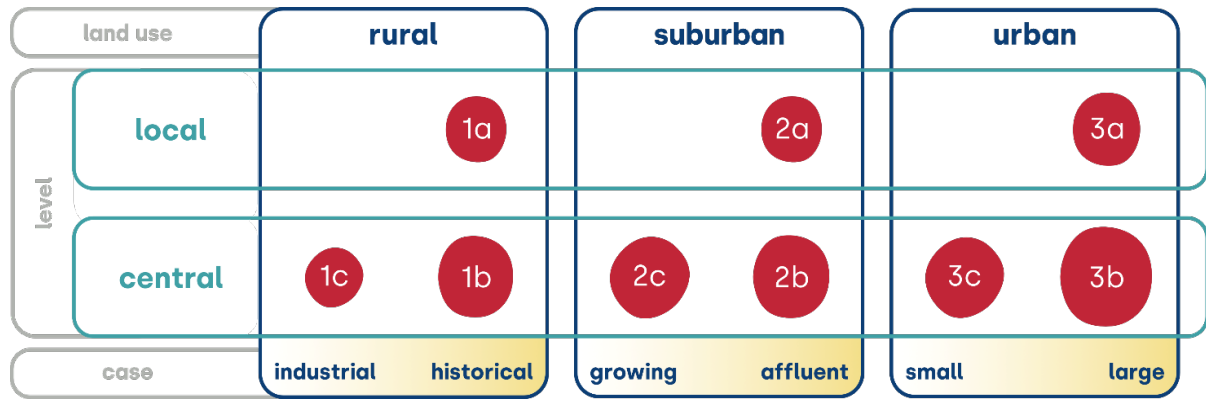

Figure 3: Typology Matrix.

Translating Data into Design Concepts

The translation framework converted insights into context-specific modules from the Typology Matrix, incorporating requirements from architecture, urban planning, design, user-experience, mobility, and other amenities (Figure 4).

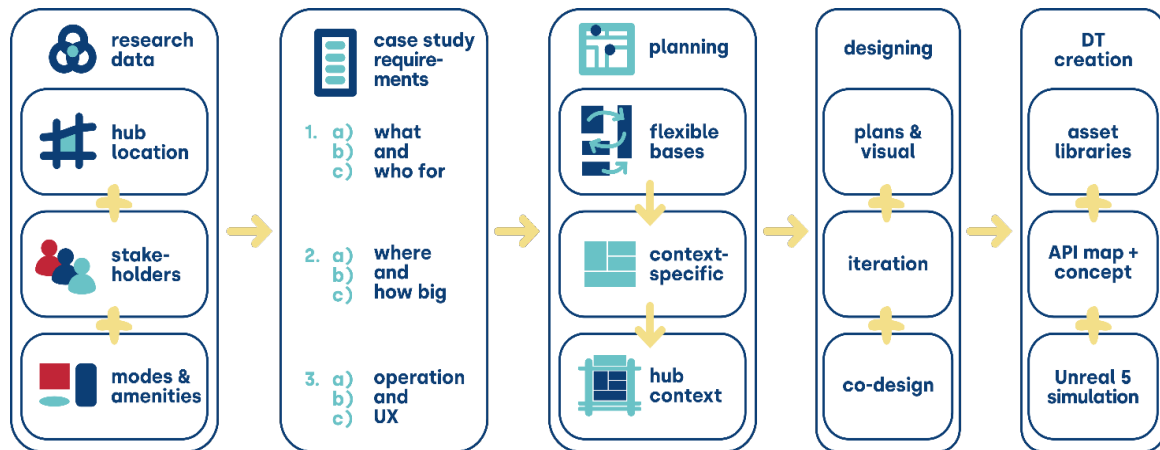

Figure 4: Translation Framework.

The design process included bubble diagrams¹⁵ (Figure 5), which translated floor plans into designs, and concept-sketching and 3D-modeling, which applied aesthetics to create hub concepts. To refine scale, collaborative AR/VR bubble exercises were conducted in Gravity Sketch. Concepts were contextualized with local datasets and validated through research feedback, ensuring designs reflected stakeholder needs and future scenarios.

Figure 5: Design Process.

¹⁵Emmons Paul, “The Cosmogony of Bubble Diagrams,” *86th Annual Association of Collegiate Schools of Architecture*, (1998): 420–25.

DT Simulation Framework

Using TwinMotion software, and following the typology matrix, DT hubs were created, each combining site topography, design concepts, animations, and environments to produce realistic, walkable, interactive, and VR-compatible simulations (Figure 6). Stakeholders could visualize pedestrian activity, multimodal traffic, architectural features, and amenities in real time. DTs enable a low-barrier entry point for discussion, aligning data, planning, and community vision into a shared language. This framework will enable further workshops where participants co-create future hubs (Figure 7).

Figure 6: DT Process.

Figure 7: Final DTs

Future Hub Playbook: A Participatory Framework for Hub Planning

The Future Hub Playbook is a participatory and data-informed tool designed to translate complex research into accessible planning resources¹⁶. This tool combines the framework from Section 3 and leverages DTs for low-cost simulations, also empowering participatory processes with diverse stakeholders by enhancing the context and leveraging data-driven mixed-use methods.

It translates the research framework into clear prompts, amenity checklists, stakeholder guides, and design concepts, enabling community leaders, planners, policymakers, companies, and nonprofits to collaboratively design future-ready hubs.

Structured for scalability and accessibility, the playbook introduces the theory of future hubs, articulating their role in addressing equity challenges, and outlining a 4-pillar step-by-step planning process for all stakeholders (Figure 8):

¹⁶“Future Mobility Design Lab,” *University of Cincinnati, Office of Research*, (2025). <https://ucdigitalfutures.com/future-mobility-design-lab/>.

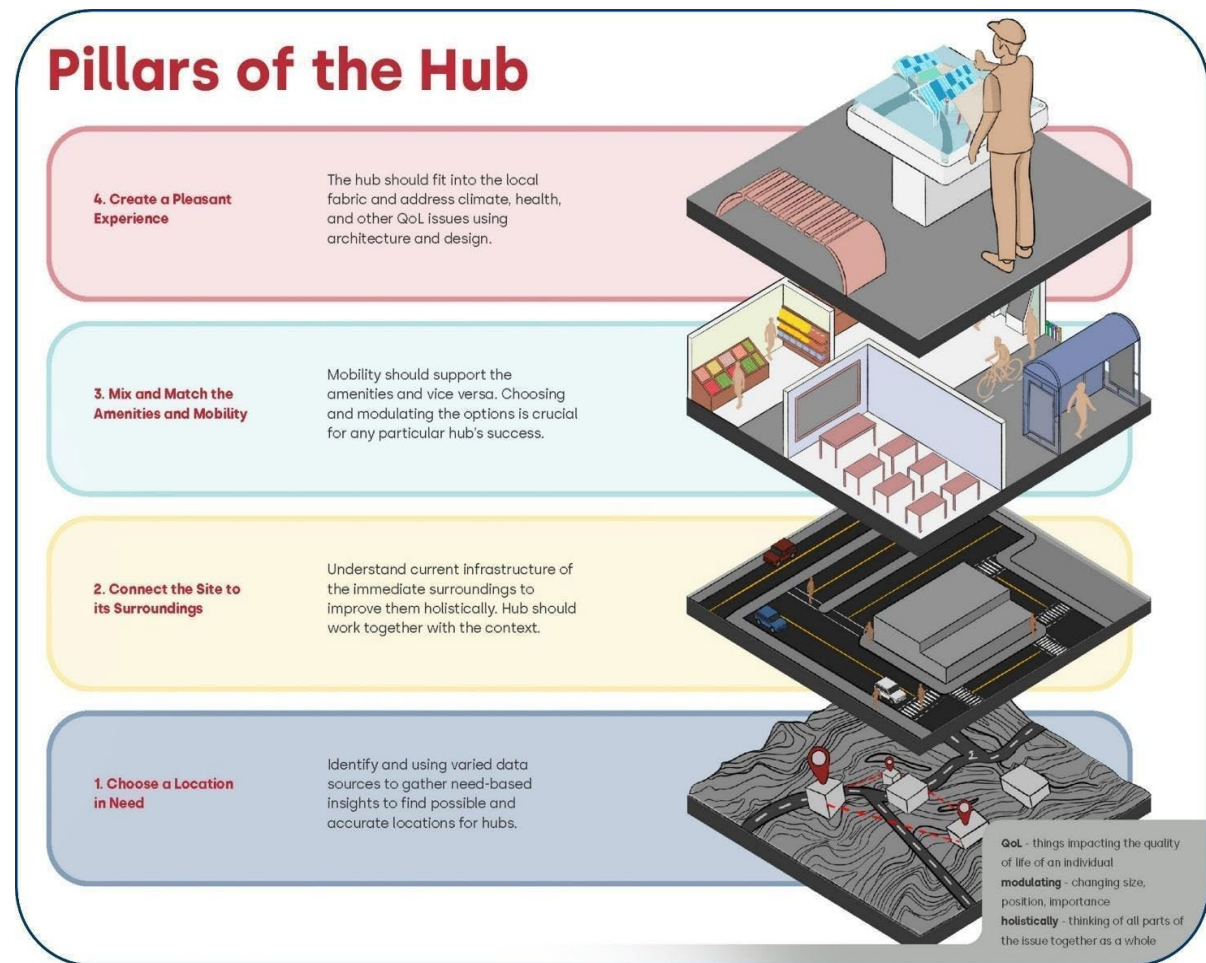

Figure 8: Hub Pillars Overview (1-Choosing location, 2-Connecting sites to surroundings, 3-Combining amenities and mobility, 4-Creating pleasant experience).

Each pillar is supported by research insights, visual DT examples, and checklists that guide stakeholders through design decisions. Rather than dictating solutions, the playbook encourages collaborative adaptation to local contexts. As both a technical and facilitation tool, it lowers barriers to civic engagement by combining HCR, data insights, and immersive technologies (Figure 9, Figure 10, Figure 11).

Although this phase is a methodological pilot, the playbook has undergone multiple revisions. ODOT experts have shown strong interest and are partnering with the FMD Lab to implement it in Ohio communities. The framework has been showcased at four regional events, including at OTEC 2024, ODOT Future Mobility and All Aboard Ohio webinars, and City of Cincinnati Port Authority demonstration. These sessions engaged planners, policymakers, transportation experts, and community members. Feedback has been overwhelmingly positive, and findings are being compiled by the FMD Lab (Figure 12).

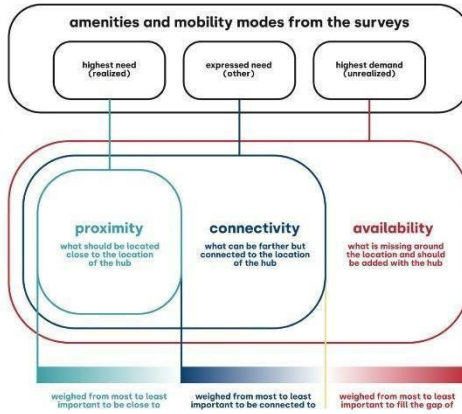

1. Choose a Location in Need

Why is this step important?
 Choosing the right location that is based on need and demand helps mobility hubs be usable to more people and businesses. It makes sure more people can get to jobs, education, healthcare, and more. Well-placed Hubs help communities grow while being financially and policy-wise efficient and sustainable.

Primary Research to Location
 Primary research helps define development priorities by gathering real-world data. Surveys, interviews, and site visits should be conducted. Utilize GIS tools to map their presence and finally cluster according to weight to uncover the right locations.

The Weighing Framework
 To cluster, the framework considers proximity, connectivity, and availability of existing mobility, infrastructure and amenities to select and weigh them. The amount of points with certain importance is used to narrow down the location. Proximity consists of places that should be within a 15-minute walk or 10 transit stops from a Hub, connectivity of places that should have smooth road or transit access, and availability of places that do not exist in the first two but should.

This framework ensures hubs are placed where they provide the most value, and make use and connect to existing places without impeding the flows of passengers and goods.

The Weighing Framework

Example of mapped existing places

Example of Clustering on a map

Consider This
 When choosing a location, consider planned land use, ensuring the hub fits current policy and into the surrounding local fabric. Evaluate current mobility options and its infrastructure to enhance connectivity and fill service gaps. Factor in surface parking lots or unused buildings' redevelopment potential to future-proof the Hub.

Action Panel!
 Use primary data early to identify specify need, demand, land use, and existing places of interest. Define which places fall into proximity, connectivity, and availability. Use publicly available GIS data to map and narrow down on the final land plots.

2c – Suburban Growing / Central Example: Forest Park, OH

About this Hub
 Forest Park, located north of Cincinnati, serves as a central hub within the suburban context due to its growing population and diverse community. Forest Park is a dynamic suburb with a mix of residential, and commercial spaces. Known for its high demographic diversity, the area is home to a blend of cultural backgrounds and socioeconomic groups. The "central" hub in Forest Park focuses on improving mobility for residents, enhancing access to essential services, and providing more sustainable transportation options. It aims to strengthen connectivity within the suburb while supporting its continued growth and development.

Figure 9: Pillars 1 and 2.

3. Mix and Match the Amenities

Why is this step important?
Selecting the right mix of amenities ensures that each hub meets the unique needs of its location and users. By considering demographics, local context, and transportation patterns, hubs can offer relevant services that enhance accessibility, usability, and community engagement.

Public Spaces
Public spaces in hubs should be designed for comfort, accessibility, and usefulness. Features like green spaces, digital kiosks, and seating areas create a welcoming environment and improve the overall experience for travelers and the community.

Essential Services
Essential services should be placed near transit areas for easy access. Amenities like grocery stores, childcare, pharmacies, and clinics help meet daily needs and support the community.

Economic Support
Economic support includes creating jobs and spaces for retail, freight, and housing. Proper placement and connections to other amenities ensure they serve the right users effectively.

Essential Services

Economic Support

Convenience

Action Panel!
Choose amenities based on user needs and local context. Balance essential services, public spaces, and commercial areas and co-locate them to the right mobility. Especially cover missing (ex. food deserts) and locally owned ones.

IoT Internet of things technology that connects devices and information into smart systems
digital kiosks - large interactive screens for any type of information or advertisement

4. Create a Pleasant Experience

Why is this step important?
Creating a pleasant experience ensures that users feel safe, comfortable, and welcomed, making their journey more enjoyable. By focusing on design elements like space, and interaction, the hub becomes a place where people can move through effortlessly, enhancing their experience and satisfaction.

Mobility Supporting the Lifestyle
Mobility should support users' daily routines through thoughtful architecture and design that provides convenient, efficient transportation options and smooth transitions between modes, ensuring easy access to essential services and amenities.

Transparency for Multimodality
Transparency in multimodality involves providing clear, real-time information about all available transportation options, routes, and schedules. Open data and integrated systems help users make informed decisions, encouraging smoother transitions between modes and increasing trust in the overall mobility network.

Quality of Life
Quality of life in mobility design means creating spaces that are easy to navigate, provide smooth access to essential services, and promote emotional well-being. Thoughtful design should minimize stress, enhance comfort, and blend seamlessly into daily life without causing disruptions.

Design Values
Incorporating elements like improved air quality, temperature control, and indigenous plants enhances environmental sustainability while creating a stronger connection to the local ecosystem. Thoughtful design can include local art, cultural references, natural light, and communal spaces to encourage social interaction and a sense of place.

Locally made and upcycled furniture

Informal spaces and space division for flexible uses

Developed storefronts for visibility

Calm community spaces for events, the unhoused, and homey feeling

Partial green roofs with solar panels for inside temperature regulation

Green and light paths and waiting with live info

Insect and animal support like beehives, local plant species, improving air quality and temperature

Covered outside spaces with art and pop-ups

Quality of Life

Conclusions: Laying the Foundation for Global Adaptation

This framework offers a replicable model that bridges local knowledge, immersive simulation, and participatory design, creating new pathways for equitable infrastructure development. Three key contributions and future work opportunities emerge:

DTs as Democratising Tools

DTs proved essential for facilitating understanding and stakeholder alignment. Their immersive realism supports data-visualisation, scenario exploration, and community engagement, making complex planning processes more inclusive. Built using game engine platforms, the nine high-fidelity DTs enabled early validations for diverse stakeholders to visualize how land-use, transportation networks, and community amenities converge. Future work includes integrating these tools into XR platforms and developing open-source frameworks for broader adoption, particularly by underserved municipalities.

Future Hub Playbook: An Empowerment Tool

The Playbook transforms research into actionable steps for a wide range of stakeholders, reframing planning as an iterative and inclusive process, empowering communities to identify priorities and engage meaningfully in co-creating context-specific hub solutions. Unlike traditional technical reports, it invites collaboration and adaptability, providing visual tools, checklists, and stakeholder prompts to support informed decision-making. Early feedback from Ohio stakeholders confirmed its scalability and potential for wider use. Future iterations will include modules for public use, training resources, and expanded digital integration.

From Ohio Pilot to Global Application

While rooted in Ohio, the framework is already being adapted globally. Current partnerships with the MIT City Science Network and regional entities in the Global South and Europe aim to adapt the methodology to new socio-political and urban contexts. Future publications will document these adaptations, with co-creation sessions, participatory evaluation, and comparative analysis. The work presented serves as the foundation for an evolving global network of case studies using the proposed core methodologies.

Acknowledgments

This work was funded by the **Ohio Department of Transportation (ODOT)**. Special thanks to Ohio communities, the **UC FMD Lab team**, and participating partners.
